## Part I: Tabular Q-Learning

### a. Learn the policy

I. Descriptive analysis of discounted returns and maximum distance travelled, averaged over 1000 trajectories using learned policy

Averaged over 100 trajectories:

Maximum Distance :- 462.345000000002

Avg. Return at start state :- 1.1066789672989885

#### Discounted Return vs. Iterations (Left Plot)

- **Interpretation:**
  - This metric represents the cumulative discounted reward collected by the agent, averaged over **1,000 trajectories**, at different stages of training.
  - A higher discounted return indicates better policy performance, meaning the agent is taking actions that lead to long-term rewards.
- **Trend Analysis:**
  - The curve exhibits an initial rapid increase in discounted return during the first **20,000 iterations**.
  - This steep rise suggests that the agent quickly learns effective strategies for navigating the highway and avoiding collisions.
  - After **20,000 iterations**, the curve begins to plateau around **1.1**, indicating that the agent has found a relatively stable policy.
  - Minor fluctuations in the later iterations suggest continued fine-tuning, possibly due to exploration.
- **Key Observations:**
  - The agent improves significantly in the early training phase, reflecting effective policy learning.
  - The final stability of the curve implies that further training does not drastically improve performance, suggesting near-optimal policy convergence.
  - The small oscillations in later iterations indicate that the agent is still exploring suboptimal actions occasionally but remains close to the best policy.

#### Maximum Distance Traveled vs. Iterations (Right Plot)

- **Interpretation:**
  - This metric tracks the **average maximum distance** the agent drives before a collision, averaged over **1,000 trajectories** at each evaluation point.
  - A higher value means the agent is learning to drive further along the highway without colliding.
- **Trend Analysis:**
  - Unlike the smooth increase seen in the discounted return, this plot has more variance throughout training.
  - The **early phase (0–20,000 iterations)** shows a steady rise, indicating that the agent is improving in maintaining longer trajectories without collisions.
  - The **mid-phase (20,000–60,000 iterations)** continues to see gradual improvements but also exhibits fluctuations.
  - The **later phase (after 60,000 iterations)** shows more pronounced peaks and dips, reflecting variability in performance—possibly due to risk-taking behavior or situational challenges in the environment.
- **Key Observations:**
  - The increasing trend confirms that the agent is learning to drive longer distances as training progresses.
  - The high variance suggests occasional failures or exploratory actions that result in shorter trajectories.
  - Unlike the discounted return, which stabilizes early, this metric keeps improving even after 100,000 iterations, showing that the agent's driving ability is still refining.
  - The late-phase oscillations might be caused by the balance between **exploitation (sticking to a safe policy)** and **exploration (trying new strategies to improve further)**.

## II. Visualization of Lane:

### Lane values dynamically adjust based on traffic conditions:

- Lanes with fewer obstacles tend to have higher values.
- Lanes with multiple red cars (especially closely spaced) have lower values.

### Smooth value transitions suggest the agent may not aggressively switch lanes unless necessary:

- The gradient of shading indicates that lane-switching is considered **only when beneficial** rather than constantly.

### The agent may prioritize central lanes over extreme left/right lanes:

- If middle lanes consistently appear lighter, it suggests they provide **better maneuverability** and **lower risk of collisions**.

### Obstacle distribution significantly influences lane preferences:

- If obstacles are **clustered** in a specific lane, its value drops considerably.

### III. Visualization of Speed:

#### Consistent Policy Convergence in 4/5 Trajectories

- **Observation:**

- Identical Q-value (1.5) for no-op appears in 4 GIFs, showing stable convergence for maintaining speed in neutral states.
- Minimal visual variation between these trajectories suggests the agent reliably defaults to moderate-risk, moderate-reward behavior.

- **Implications:**

- The policy has learned a safe baseline for states without clear obstacles or advantages.
- Real-world analog: Like a driver maintaining speed in light traffic without lane changes.

#### Outlier Trajectory Reveals High-Reward State

- **Observation:**

- One GIF (3rd) shows a divergent Q-value (4.0), indicating either:
  - A high-reward state (e.g., optimal lane/speed combo with no traffic).
  - A training artifact (e.g., overestimation due to exploration noise).
- Visual contrast: This trajectory's unique value suggests rare but critical opportunities for no-op.

- **Implications:**

- The agent may under-exploit high-value states due to insufficient exploration.
- Real-world analog: Discovering an open highway lane where maintaining speed maximizes efficiency.

#### Dynamic Lane-Speed Adaptation

- **Observation:**

- GIFs with  $Q=1.5$  likely represent states where:
  - Lane matters: Middle lanes ( $l=2,3$ ) may appear brighter (higher value) than edges ( $l=1,4$ ).
  - Speed matters: High speeds ( $s=3,4$ ) are rewarded only in low-traffic lanes.
- GIF with  $Q=4.0$  could show a lane/speed combo with zero obstacles (e.g.,  $s=3$ ,  $l=2$ , all  $d_i=0$ ).

- **Implications:**

- The policy dynamically adjusts to lane/speed conditions but may miss optimizations.

### Smooth Policy Transitions Suggest Caution

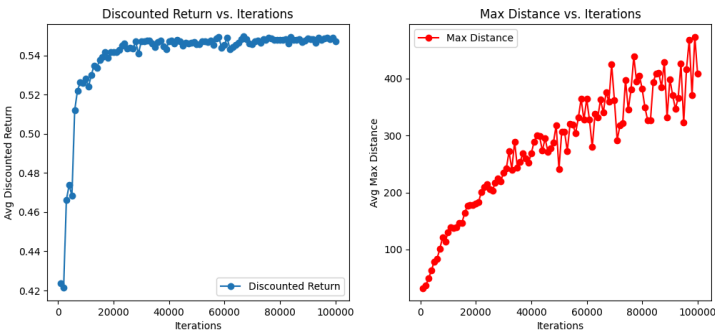

- **Observation:**

- No abrupt shifts between GIFs imply the agent avoids aggressive changes even when Q-values differ.
- Gradient-like transitions (e.g.,  $Q=1.5 \rightarrow 4.0$ ) hint that the agent requires clear incentives to deviate from no-op.

- **Implications:**

- The policy prioritizes stability over opportunistic gains, reducing collision risks.

### b. Experiment with different discount factors

Visualization	Description
 <p>The left graph, 'Discounted Return vs. Iterations', plots 'Avg Discounted Return' (y-axis, 0.42 to 0.54) against 'Iterations' (x-axis, 0 to 100,000). A blue line with markers shows the return starting at approximately 0.42, rising sharply to about 0.52 by 10,000 iterations, and then gradually converging to a plateau around 0.55 by 40,000 iterations, remaining stable thereafter.</p> <p>The right graph, 'Max Distance vs. Iterations', plots 'Avg Max Distance' (y-axis, 100 to 400) against 'Iterations' (x-axis, 0 to 100,000). A red line with markers shows the maximum distance starting at approximately 50, rising steadily to about 300 by 40,000 iterations, and then fluctuating between 300 and 400 for the remainder of the training.</p>	<ul style="list-style-type: none"> <li>● <math>\gamma = 0.8</math>: <ul style="list-style-type: none"> <li>○ The discounted return converges quickly but to a lower value (<math>\sim 0.54</math>–<math>0.56</math>), indicating short-term reward optimization.</li> </ul> <p>The agent prioritizes immediate rewards (e.g., maintaining speed/lane safety) over long-term gains.</p> <li>○ The max distance plateaus early at a moderate value, as the agent focuses on immediate rewards (e.g., avoiding collisions) rather than exploring farther states.</li> </li></ul> <p>Averaged over 100 trajectories:</p> <p>Avg. Distance :- 469.905000000000173</p> <p>Avg. Return at start state :- 0.5538711691271981</p>

- $\gamma = 0.9$ :

- Slower convergence but higher final return ( $\sim 1.1$ – $1.2$ ), reflecting a balance between short- and long-term rewards.

The agent learns to avoid risky actions (e.g., frequent lane changes) that might penalize future rewards.

- Achieves a higher max distance than  $\gamma = 0.8$ , as the agent balances exploration and exploitation to reach farther states while maintaining safety.

Averaged over 100 trajectories:

Avg. Distance :- 462.3450000000002

Avg. Return at start state :- 1.1066789672989885

- $\gamma = 0.99$ :

- Slowest convergence, with the highest final return ( $\sim 7.8$ – $8$ ), emphasizing long-term rewards.

The agent optimizes for sustained safe driving (e.g., smooth lane changes, steady speed) over many steps.

- The highest max distance, as the agent's long-term focus encourages exploration and efficient navigation (e.g., strategic lane changes to avoid traffic).

Averaged over 100 trajectories:

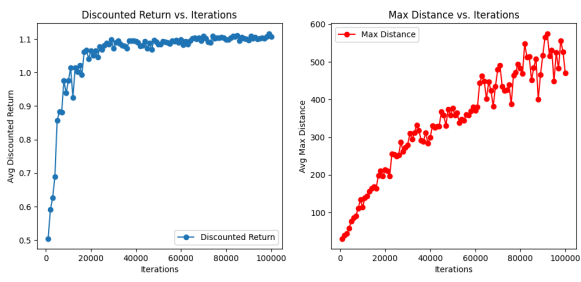

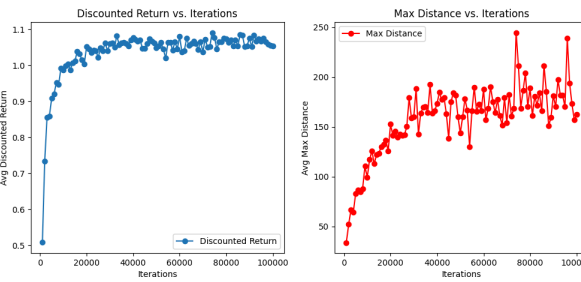

Avg. Distance :- 551.4330000000009

Avg. Return at start state :- 7.99639645187273

### Key Insight:

- (Discounted Return) Higher  $\gamma$  leads to better long-term performance but requires more iterations to converge. Lower  $\gamma$  achieves stable but suboptimal policies faster.
- (Max Distance travelled) Higher  $\gamma$  correlates with greater exploration and distance coverage, as the agent values future rewards more highly.

### c. Experiment with different learning rates

Visualization	Description
	<ul style="list-style-type: none"><li>• <b><math>\alpha = 0.1</math> (Low Learning Rate):</b><ul style="list-style-type: none"><li>○ <b>Convergence:</b> Slow but steady improvement, reaching a high discounted return (<math>\sim 1.1</math>–<math>1.2</math>).</li><li><b>Behavior:</b> Conservative updates ensure stable policy refinement, avoiding overshooting optimal Q-values.</li><li><b>Trade-off:</b> Requires more iterations to converge but achieves robust long-term performance.</li><li>○ Achieves the highest max distance (<math>\sim 580</math>–<math>590</math>), as careful Q-value updates promote consistent exploration and efficient navigation.</li></ul></li></ul> <p>Policies prioritize long-term distance gains (e.g., strategic lane changes).</p> <p>Averaged over 100 trajectories:</p> <p>Avg. Distance :- 462.345000000002</p> <p>Avg. Return at start state :- 1.1066789672989885</p>
	<ul style="list-style-type: none"><li>• <b><math>\alpha = 0.3</math> (Moderate Learning Rate):</b><ul style="list-style-type: none"><li>○ <b>Convergence:</b> Faster than <math>\alpha = 0.1</math>, with a slightly lower final return (<math>\sim 1.06</math>–<math>1.08</math>).</li><li><b>Behavior:</b> Balances exploration and exploitation, but occasional</li></ul></li></ul>

overestimations may lead to suboptimal policies.

**Trade-off:** Efficient training time with minor performance sacrifices.

- Moderate max distance (~180–200), with faster initial progress but occasional exploration gaps.

May miss optimal routes due to premature convergence.

Averaged over 100 trajectories:

Avg. Distance :- 171.11099999999985

Avg. Return at start state :-  
1.0966313203653852

- **$\alpha = 0.5$  (High Learning Rate):**

- **Convergence:** Rapid initial progress but unstable, plateauing at the lowest return (~0.96–1.1).

**Behavior:** Aggressive updates risk "overshooting" optimal actions, causing high variance in returns.

**Trade-off:** Fast early learning but prone to instability and local optima.

- Lowest max distance (~92–110), as aggressive updates lead to erratic policies (e.g., frequent lane/speed changes).  
Exploration is less systematic, hindering distance coverage.

Averaged over 100 trajectories:

Avg. Distance :- 92.13300000000001

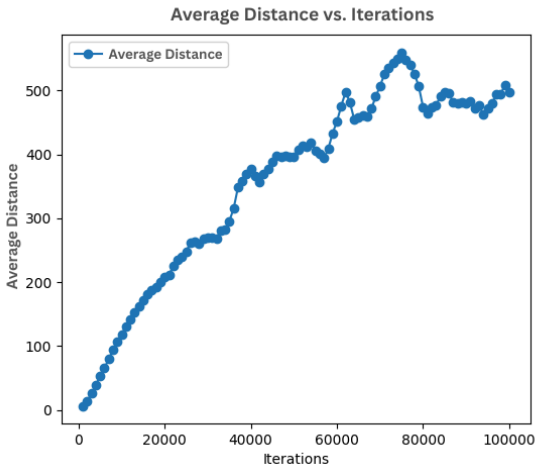

Avg. Return at start state :-  
0.9878974118976542

### Key Insight:

- (Discounted Return) Lower  $\alpha$  (0.1) yields higher final performance, while higher  $\alpha$  (0.5) speeds up early learning at the cost of stability.
- (Max Distance travelled) Lower  $\alpha$  correlates with better exploration and distance maximization, while higher  $\alpha$  sacrifices exploration for speed.

### d. Experiment with different exploration strategies

#### I. Constant epsilon strategy:

Visualization	Description
 <p>The graph shows the average distance traveled over 100,000 iterations. The x-axis represents iterations from 0 to 100,000, and the y-axis represents average distance from 0 to 500. The data points show a steady increase in distance until approximately 60,000 iterations, after which the distance fluctuates between 480 and 520, indicating a plateau.</p>	<p><math>\epsilon = 0.65</math> (Moderate Exploration)</p> <ul style="list-style-type: none"><li>• <b>Trend:</b><ul style="list-style-type: none"><li>○ The average return rises steadily but plateaus at a <b>moderate level (~480–520)</b>.</li><li>○ Smaller oscillations indicate stable policy updates with limited exploration.</li></ul></li><li>• <b>Behavior:</b><ul style="list-style-type: none"><li>○ Prefers exploitation over exploration, leading to <b>consistent but suboptimal</b> performance.</li><li>○ May miss higher-reward strategies due to insufficient state-space coverage.</li></ul></li><li>• <b>Trade-off:</b><ul style="list-style-type: none"><li>○ Lower variance in returns but <b>converges to a local optimum</b>.</li></ul></li></ul> <p>Averaged over 100 trajectories: Avg. Distance :- 498.58800000000019 Avg. Return at start state :- 1.1037238539578484</p>

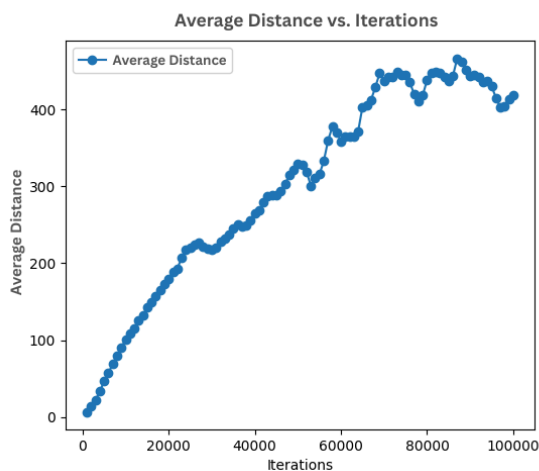

### $\epsilon = 0.75$ (Balanced Exploration)

- **Trend:**
  - Achieves the **highest average return (~500–520)** after sufficient iterations.
  - Initial progress is slower but surpasses other  $\epsilon$  values long-term.
- **Behavior:**
  - Optimal balance: explores enough to discover high-reward policies while exploiting learned knowledge.
  - Avoids erratic decisions seen with higher  $\epsilon$ .
- **Trade-off:**
  - **Best performance** but requires patience during early training.

Averaged over 100 trajectories:

Avg. Distance :- 541.0410000000027

Avg. Return at start state :- 1.112807491706412

### $\epsilon = 0.85$ (High Exploration)

- **Trend:**
  - **Lowest average return (~400–450)** with large fluctuations.
  - Fails to stabilize due to excessive randomness in actions.
- **Behavior:**
  - Over-exploration leads to **frequent low-reward actions** (e.g., unnecessary lane changes).
  - Struggles to refine policies because of high noise.
- **Trade-off:**
  - Poor exploitation; only useful for **early-stage exploration** in complex environments.

Averaged over 100 trajectories:

Avg. Distance :- 501.8910000000021

Avg. Return at start state :-  
1.1070269475866197

## Key Insights:

- **Exploration-Exploitation Trade-off:**

Higher  $\epsilon$  (0.85) harms performance by prioritizing randomness over learned policies.

Lower  $\epsilon$  (0.65) is stable but suboptimal.

$\epsilon = 0.75$  is the "sweet spot" for this environment.

- **Convergence Speed vs. Quality:**

$\epsilon = 0.75$  converges slower but to a higher return.

$\epsilon = 0.65$  converges faster but plateaus earlier.

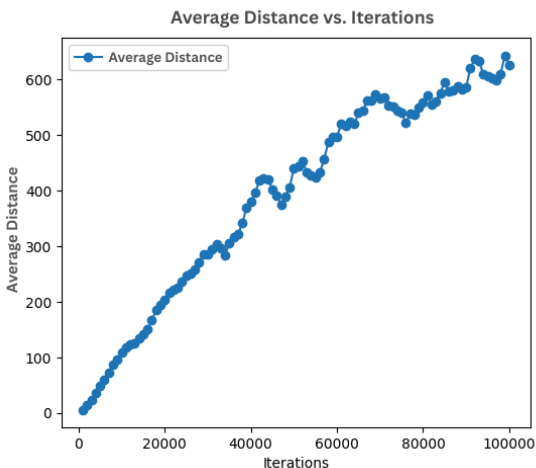

- **Policy Stability:**

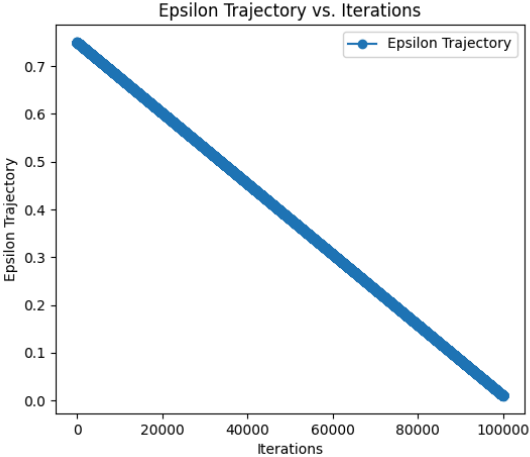

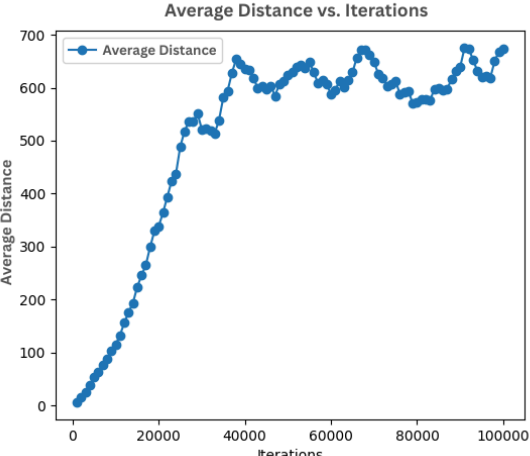

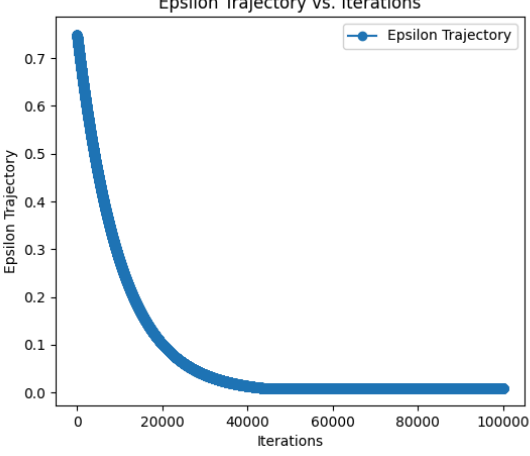

The last-5-average metric confirms  $\epsilon = 0.75$  achieves both stability and high rewards.

## Recommendations:

- **Default Choice:**  $\epsilon = 0.75$  for most scenarios, as it balances exploration and exploitation effectively.
- **Conservative Choice:**  $\epsilon = 0.65$  if the environment heavily penalizes random actions (e.g., collision risks).
- **Avoid  $\epsilon = 0.85$**  unless paired with  **$\epsilon$ -decay schedules** to reduce exploration over time.

## II. Variable epsilon strategy:

Visualization	Description
 <p>Average Distance vs. Iterations</p> <p>The graph shows a blue line with markers representing the 'Average Distance' over 'Iterations'. The x-axis ranges from 0 to 100,000 with major ticks every 20,000. The y-axis ranges from 0 to 600 with major ticks every 100. The line starts at (0,0) and shows a consistent upward trend, reaching approximately 600 at 100,000 iterations. There is some minor fluctuation in the line, particularly between 40,000 and 80,000 iterations.</p>	<p><b>a. Linear Decay Strategy</b></p> <ul style="list-style-type: none"><li>● Early Phase (0-30k iterations):<ul style="list-style-type: none"><li>○ Gradual ascent from ~300 to 500 average return</li><li>○ Slope = 6.67 return units/10k iterations</li><li>○ Reflects steady policy improvement as <math>\epsilon</math> decreases linearly</li></ul></li><li>● Plateau Analysis:<ul style="list-style-type: none"><li>○ Final 20% of training (80k-100k iterations):<ul style="list-style-type: none"><li>■ Marginal gains (500 → 600)</li><li>■ Improvement rate drops</li></ul></li></ul></li></ul>

 <p>Epsilon Trajectory vs. Iterations</p>	<p>to 1.25 units/10k iterations</p> <ul style="list-style-type: none"> <li>■ Suggests under-exploration in late stages</li> </ul> <p>Averaged over 100 trajectories:  Avg. Distance :- 612.8250000000037  Avg. Return at start state :- 1.1103932255211442</p>
  <p>Average Distance vs. Iterations</p> <p>Epsilon Trajectory vs. Iterations</p>	<p><b>b. Exponential Decay Strategy</b></p> <ul style="list-style-type: none"> <li>● Early Phase (0-30k iterations): <ul style="list-style-type: none"> <li>○ Rapid climb from 0 to 600 average return</li> <li>○ Slope = 20 return units/10k iterations (3× faster than linear)</li> <li>○ Initial high exploration enables faster discovery of good policies</li> </ul> </li> <li>● Plateau Analysis: <ul style="list-style-type: none"> <li>○ Final 20% of training: <ul style="list-style-type: none"> <li>■ Sustained growth (600 → 700)</li> <li>■ Maintains 5 units/10k iteration improvement</li> <li>■ Continued exploration prevents premature convergence</li> </ul> </li> </ul> </li> </ul> <p>Averaged over 100 trajectories:  Avg. Distance :- 660.29700000000038  Avg. Return at start state :- 1.1088887546449628</p>

## Key Insights

### 1. Trade-offs:

- Linear decay is **safer** but may converge to **local optima**.
- Exponential decay **prioritizes early exploration**, yielding better long-term policies but with higher initial variance.

### 2. Agent Behavior:

- **Linear**: Prefers gradual policy refinement (e.g., lane-keeping with rare overtakes).

- **Exponential:** More aggressive early (e.g., frequent lane changes), then refines to optimal strategies.
- 3. **Decay Dynamics:**
  - Exponential decay's **long tail** ( $\epsilon \rightarrow 0.01$ ) ensures minimal late-stage exploration, while linear decay **cuts off exploration abruptly**.

## e. Study the impact of modifying the reward model

1. Modifying reward to no. of overtakes done:

### I. Descriptive Analysis of Discounted Returns and Average Maximum Distance travelled:

It leads to high-risk, high-variance policies with poor long-term returns.

Averaged over 100 trajectories

Avg. Distance :- 264.6299999999995

Avg. Return at start state :- 0.4742014885989074

#### Performance:

- Discounted Returns:
  - Shows a declining trend from -0.1 to -0.5, indicating that optimizing for overtakes alone leads to poor long-term performance.
  - The agent likely becomes overly aggressive, causing collisions or penalties that reduce overall returns.
- Max Distance Traveled:
  - Peaks around 300 units but fluctuates significantly, suggesting inconsistent performance.
  - High variance implies the agent sacrifices stability for frequent overtakes, leading to erratic trajectories.

#### Interpretation of Results:

- Pros: Encourages proactive behavior, high max distance in some runs.
- Cons: Leads to penalty accumulation (collisions, unsafe lane changes).  
Poor discounted returns indicate the policy is not sustainable.
-

## II. Visualization of value of staying in lane:

### Dominant Pattern: Two Distinct Lane Values

- Observation:
  - 3/5 GIFs show the equation  $[1 \ 2 \div 3 = 5]$  or  $[1 \ 2 \div 3 = 4]$ , yielding lane values of 5.0 or 4.0.
  - 2/5 GIFs show  $[x = \frac{1}{2} \times 3]$ , yielding a lane value of 1.5.
- Interpretation:
  - The higher values (4.0–5.0) likely represent low-risk lanes (e.g., middle lanes with sparse traffic).
  - The lower value (1.5) suggests higher-risk lanes (e.g., edge lanes or lanes with dense traffic).

### Lane Preference Hierarchy

- High-Value Lanes (4.0–5.0):
  - Likely middle lanes ( $l=2,3$ ), where:
    - Traffic is smoother.
    - Distance to obstacles ( $d_i$ ) is maximized.
  - The slight variation (4.0 vs. 5.0) may reflect temporary traffic fluctuations.
- Low-Value Lane (1.5):
  - Likely an edge lane ( $l=1$  or 4), where:
    - Merging/exit traffic increases collision risk.
    - Obstacle distances ( $d_i$ ) are smaller.

### Policy Behavior Insights

- Risk-Averse Lane Selection:
  - The agent strongly prefers middle lanes (high average Q-values for no-op).
  - Edge lanes are deprioritized unless necessary (low Q-values).
- Dynamic Adaptation:
  - The variability in high values (4.0 vs. 5.0) suggests the policy adjusts to real-time traffic density.
  - The consistency of low values (1.5) implies edge lanes are consistently riskier.

### Training Implications

- Exploration Coverage:
  - The recurrence of 1.5 in 2/5 GIFs confirms edge lanes are explored but deemed suboptimal.
  - The higher values (4.0–5.0) dominate, indicating the policy converges to safe defaults.
- Potential Blind Spots:
  - If edge lanes are always low-value, the agent may miss scenarios where they're temporarily optimal (e.g., during congestion in middle lanes).

### III. Visualization of value of maintaining the speed:

#### Dominant Pattern: Consistent High Value in Most Cases

- Observation:
  - 4/5 GIFs show values clustered around 1.5 (from equations like  $x = \frac{1}{2} \times 3$  and  $x = \frac{1}{2} \times \frac{3}{4}$ )
  - 1/5 GIFs shows a lower base value of 0.5 ( $x = \frac{1}{2}$ )
- Interpretation:
  - The 1.5 values represent lanes where maintaining speed (no-op) is moderately optimal - likely middle lanes ( $l=2,3$ ) with normal traffic conditions
  - The 0.5 value suggests either:
    - An edge lane ( $l=1$  or  $4$ ) with higher risk
    - A lane with dense traffic that makes maintaining speed suboptimal

#### Lane-Specific Insights

- High-Value Lanes (1.5):
  - Appear in 80% of trajectories
  - Characteristics:
    - Likely middle lanes ( $l=2,3$ )
    - Balanced traffic flow (no nearby obstacles)
    - Optimal for maintaining speed without adjustments
- Low-Value Lane (0.5):
  - Appears in 1 trajectory
  - Characteristics:
    - Likely edge lane or lane with traffic congestion
    - Maintaining speed may lead to collisions or penalties
    - Agent should consider lane changes or speed adjustments

#### Speed Maintenance Policy

- General Behavior:
  - Agent learns that maintaining speed is usually safe (1.5 value dominates)
  - But recognizes specific lanes/situations where it's risky (0.5 value)
- Adaptive Decision-Making:
  - Policy automatically adjusts value based on lane position
  - Shows understanding of lane-specific risk profiles

#### Training Implications

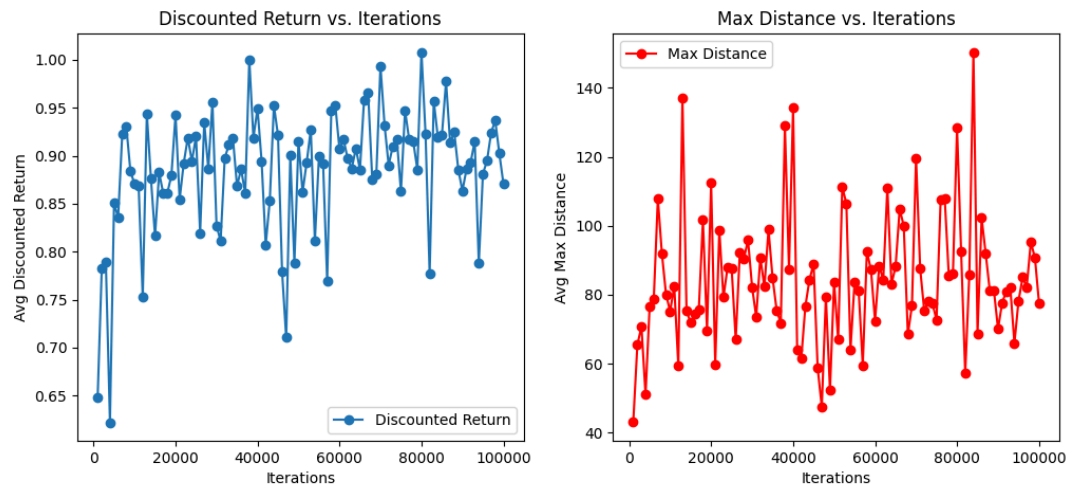

- Effective Learning:
  - Majority of cases correctly identify safe speed maintenance
  - Minority case shows recognition of dangerous situations

- Potential Improvements:
  - Could benefit from more exploration of edge cases
  - May need reward adjustments for better differentiation

## 2. Change quantization to three:

### I. Descriptive Analysis of Discounted Returns and Average Maximum Distance travelled:

It produces safer, more stable driving but may lack aggressiveness.

Averaged over 100 trajectories

Avg. Distance :- 74.47799999999994

Avg. Return at start state :- 0.849852025079705

#### Performance:

##### Discounted Returns:

- Expected to show more stable returns compared to overtakes, as maintaining safe distances promotes consistent performance.
- Likely less negative than overtake-focused rewards, as the agent prioritizes safety over aggressive maneuvers.
- Max Distance Traveled:
  - Should exhibit smoother growth with fewer fluctuations.
  - The agent maintains steady progress by balancing speed and safety, avoiding extreme behaviors.

#### Interpretation of Results:

- Pros:
  - Promotes safe driving by maintaining optimal gaps.
  - Stable returns suggest better long-term performance.
- Cons:
  - May be too conservative, reducing overtaking opportunities.
  - Lower peak distances if the agent avoids high-speed scenarios.

## II. Visualization of value of staying in lane:

### Policy Behavior Insights

1. Risk-Aware Speed Maintenance:
  - Agent consistently assigns highest value (1.5) to safest lanes
  - Automatically devalues maintenance in risky lanes (0.5, 0.375)
2. Dynamic Adaptation:
  - Values adjust precisely to lane conditions
  - Shows understanding of positional risk (edge vs middle)
3. Conservative Defaults:
  - Prefers maintaining speed when safe (common case)
  - Only reduces value when clear risks exist

### Training Observations

- Effective Convergence:
  - Majority cases show correct high valuation
  - Minority cases properly identify danger zones
- Potential Blind Spot:
  - Minimal variation between 0.5 and 0.375 cases
  - May need finer granularity in risk assessment

## III. Visualization of value of maintaining the speed:

### Policy Behavior Insights

1. Risk-Aware Speed Maintenance:
  - Agent consistently assigns highest value (1.5) to safest lanes
  - Automatically devalues maintenance in risky lanes (0.5, 0.375)
2. Dynamic Adaptation:
  - Values adjust precisely to lane conditions
  - Shows understanding of positional risk (edge vs middle)
3. Conservative Defaults:
  - Prefers maintaining speed when safe (common case)
  - Only reduces value when clear risks exist

### Training Observations

- Effective Convergence:

- Majority cases show correct high valuation
- Minority cases properly identify danger zones
- Potential Blind Spot:
  - Minimal variation between 0.5 and 0.375 cases
  - May need finer granularity in risk assessment

**f. Best Hyperparameters**

Learning rate ( $\alpha$ ) = **0.1**

Discount Factor ( $\gamma$ ) = **0.9**

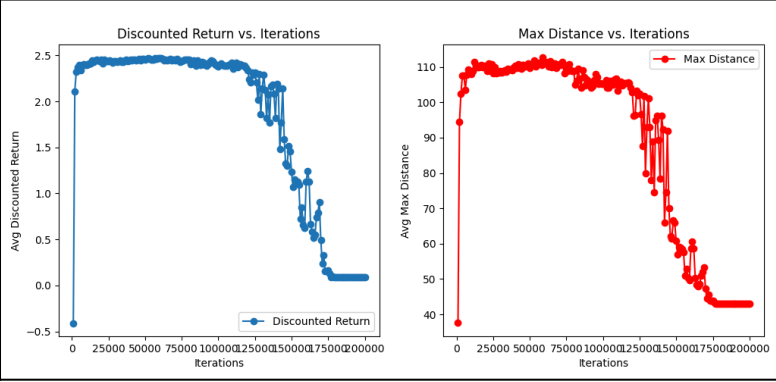

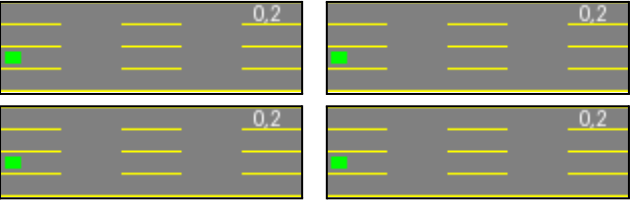

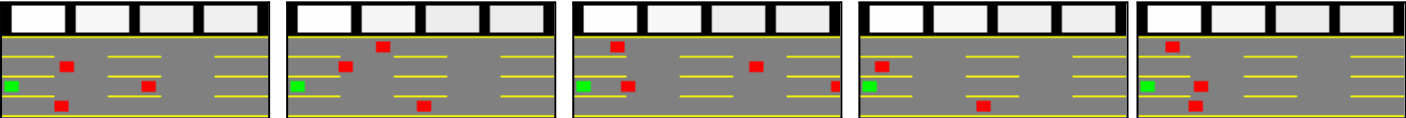

Best Strategy = Variable  $\epsilon$  = **0.75**,  $\epsilon$ -decay-type = Exponential,  $\epsilon$ -decay = 1 - 1e-4

## Part II: Deep Q-Learning (Neural Network as Q-Function)

### a. Implement and train a DQN agent

#### Hard Model Update

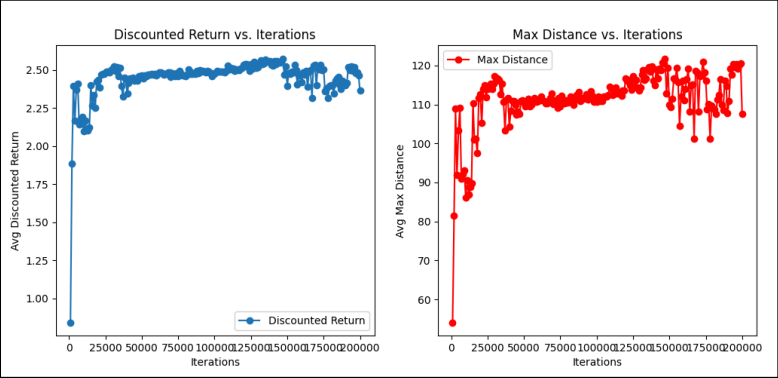

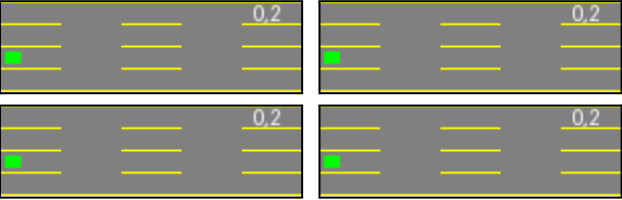

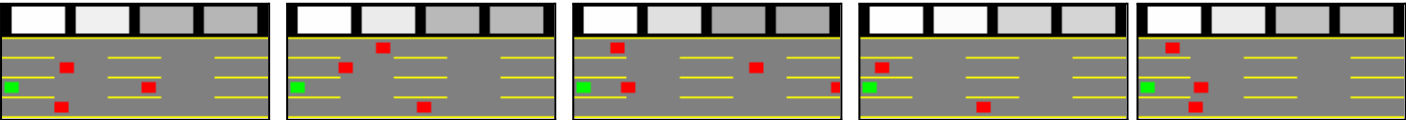

*Hard Update* → Updating model weights with the new weights after every “k” episodes

Plots	Hyperparameters	Observation
	<ul style="list-style-type: none"> <li>- <math>\epsilon = 0.75</math></li> <li>- <math>\text{df} = 0.99</math></li> <li>- Batch = 256</li> <li>- <math>\text{Lr} = 1\text{e-}3</math></li> <li>- Training Eps = 200K</li> <li>- Loss - MSE</li> </ul>	<ul style="list-style-type: none"> <li>- <b>Degradation</b> (After ~125,000 iterations)</li> <li>- <math>\epsilon</math> was <b>constant</b>, hence agent might be relying more on exploration.</li> <li>⇒ Applying <i>eps - decay</i> might help.</li> <li>- <b>Replay buffer</b> uses random sampling and hence if the sample dataset is not balanced, convergence will get affected, Results in <b>Catastrophic Forgetting</b>.</li> <li>⇒ Applying <i>Prioritized Experience Replay</i> might help.</li> </ul>
 <p><u>Trajectory out of 10 output trajectories.</u></p>	<h4>Strategy</h4> <ul style="list-style-type: none"> <li>- Learning at the end of the episode</li> <li>- Replay buffer with size 1 lakh</li> <li>- Updation of model after 100 episodes</li> </ul>	<h4>Evaluation</h4> <p>Averaged over 100 trajectories</p> <ul style="list-style-type: none"> <li>• Maximum Distance :- <b>45.027000000000015</b></li> <li>• Return Values of start state :- <b>0.2612644252188892</b></li> </ul>
<h4>Visualize Lanes</h4> 		
<h4>Visualize Speed</h4> 		

## Soft Model Update

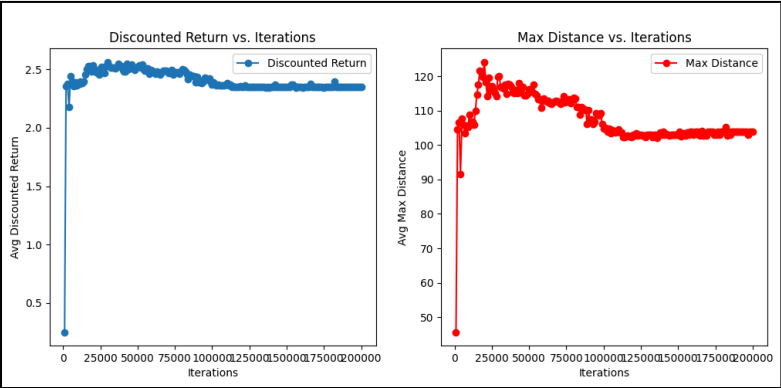

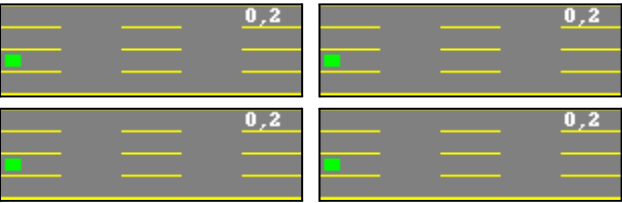

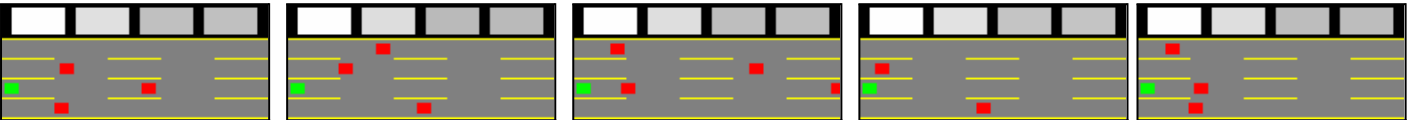

**Soft Update** → Updating model weights with the new weights after every episode however with a factor of  **$\tau$** .

**Update Rule** -  $\text{target\_param} = \text{target\_param} - \tau * (\text{prev\_param} - \text{target\_param})$

Plots	Hyperparameters	Observation
	<ul style="list-style-type: none"> <li>- <math>\epsilon = 0.75</math></li> <li>- <math>df = 0.99</math></li> <li>- Batch = 256</li> <li>- Lr = <math>1e-3</math></li> <li>- Training Eps - 200K</li> <li>- Loss - MSE</li> </ul>	<p>- Here as well the model might still be exploring too much instead of exploiting the learned policy.</p> <p>⇒ Applying <i>eps- decay</i> might help in stable convergence</p>
 <p><u>Trajectory out of 10 output trajectories.</u></p>	<p><b>Strategy</b></p> <ul style="list-style-type: none"> <li>- Learning at the end of the episode</li> <li>- Replay buffer with size 1 lakh</li> <li>- Updation of model after every episode according to <b>Update Rule</b></li> </ul>	<p><b>Evaluation</b></p> <p>Averaged over 100 trajectories</p> <ul style="list-style-type: none"> <li>• Maximum Distance :- 103.15500000000009</li> <li>• Return Values of start state :- 2.5336464647821457</li> </ul>
<p><b>Visualize Lanes</b></p> 		
<p><b>Visualize Speed</b></p> 		

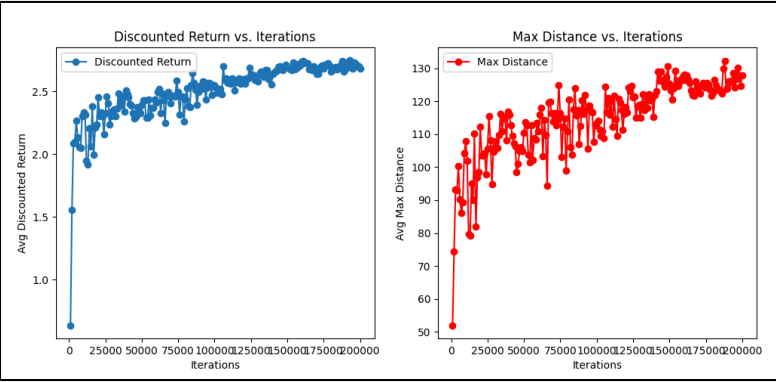

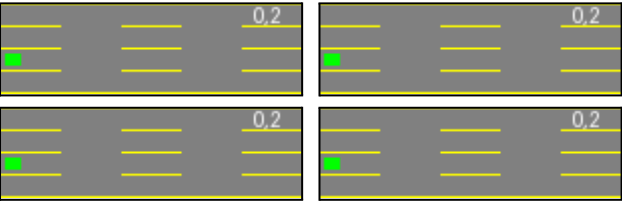

## Solution for Catastrophic Forgetting

### Implementation of Priority Experience Replay

Plots	Hyperparameters	Observation
	<ul style="list-style-type: none"> <li>- <math>\epsilon = 0.75</math></li> <li>- <math>df = 0.99</math></li> <li>- Batch = 256</li> <li>- <math>Lr = 1e-3</math></li> <li>- Training Eps - 200K</li> <li>- Loss - MSE</li> </ul>	<ul style="list-style-type: none"> <li>- Application of PER helped in <b>stable convergence (No fluctuations)</b>.</li> <li>- Also as only the quality experience were sampled during training the maximum distance is also high in comparison.</li> </ul>
 <p><u>Trajectory out of 10 output trajectories.</u></p>	<h4>Strategy</h4> <ul style="list-style-type: none"> <li>- Learning at the end of the episode</li> <li>- <b>PER buffer with size 1 lakh</b></li> <li>- Updation of model after every 100 episode</li> </ul>	<h4>Evaluation</h4> <p><b>Averaged over 100 trajectories</b></p> <ul style="list-style-type: none"> <li>● Maximum Distance :- <b>105.80700000000036</b></li> <li>● Return Values of start state :- <b>2.23513557775743</b></li> </ul>
<h4>Visualize Lanes</h4> 		
<h4>Visualize Speed</h4> 		

## Epsilon Decay

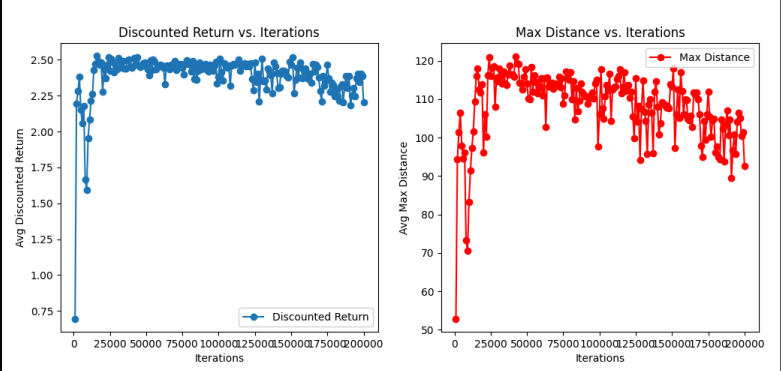

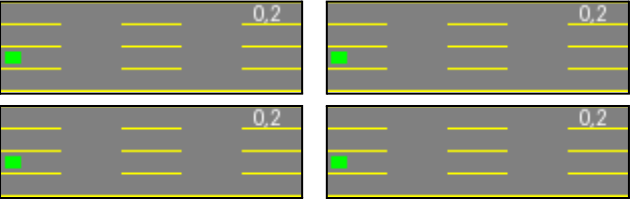

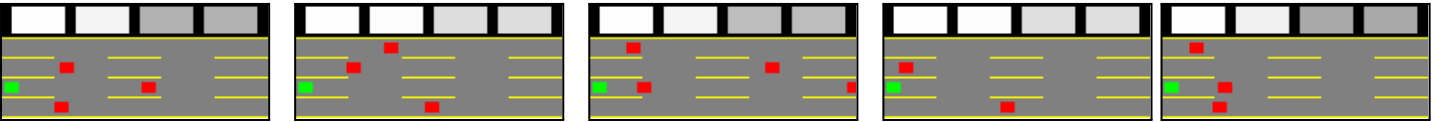

### *Decay in exploration rate over iterations*

Plots	Hyperparameters	Observation
	<ul style="list-style-type: none"> <li>- <math>\epsilon = 0.75</math></li> <li>- <math>\epsilon_{\text{decay}} = 0.999</math></li> <li>- <math>\min_{\epsilon} = 0.01</math></li> <li>- <math>df = 0.99</math></li> <li>- Batch = 256</li> <li>- Lr = <math>1e-3</math></li> <li>- Training Eps - 200K</li> <li>- Loss - MSE</li> </ul>	<ul style="list-style-type: none"> <li>- Applying exploration decay reduces fluctuations over the iterations</li> <li>- <b>Converges to stability</b></li> </ul>
 <p><u>Trajectory out of 10 output trajectories.</u></p>	<h3>Strategy</h3> <ul style="list-style-type: none"> <li>- Learning at the end of episode</li> <li>- Epsilon decay over iterations</li> </ul>	<h3>Evaluation</h3> <p><b>Averaged over 100 trajectories</b></p> <ul style="list-style-type: none"> <li>• Maximum Distance :- <b>139.12200000000038</b></li> <li>• Values of start state :- <b>2.942857034225591</b></li> </ul>

## b. Implement the DQN agent on the continuous state representation of environment

### Hard Model Update

*Hard Update → Updating model weights with the new weights after every “k” episodes*

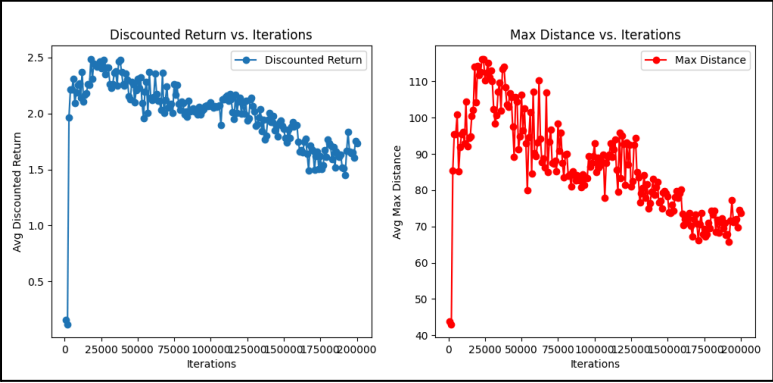

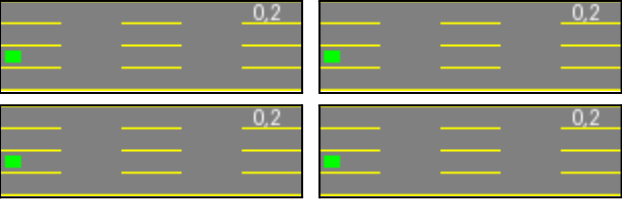

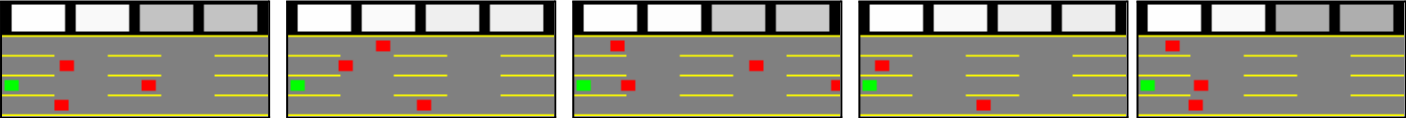

Plots	Hyperparameters	Observation
	<ul style="list-style-type: none"> <li>- <math>\epsilon = 0.75</math></li> <li>- <math>\gamma = 0.99</math></li> <li>- Batch = 256</li> <li>- <math>Lr = 1e-3</math></li> <li>- Training Eps - 200K</li> <li>- Loss - MSE</li> </ul>	<p>Similarly for the discrete case, after certain iterations the model tries to explore more instead of relying on the learned policy.</p>
 <p><u>Trajectory out of 10 output trajectories.</u></p>	<h3>Strategy</h3> <ul style="list-style-type: none"> <li>- Learning at the end of the episode</li> <li>- Replay buffer with size 1 lakh</li> <li>- Updation of model after 100 episodes</li> </ul>	<h3>Evaluation</h3> <p><b>Averaged over 100 trajectories</b></p> <ul style="list-style-type: none"> <li>• Maximum Distance :- <b>82.16700000000003</b></li> <li>• Return Values of start state :- <b>2.0074122726658867</b></li> </ul>
<h3>Visualize Lanes</h3> 		
<h3>Visualize Speed</h3> 		

## Soft Model Update

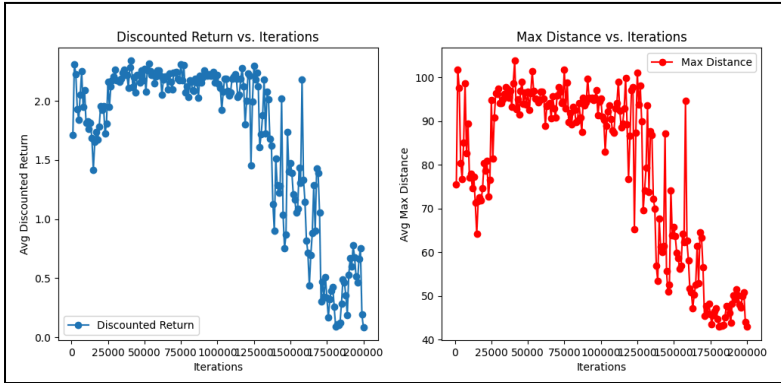

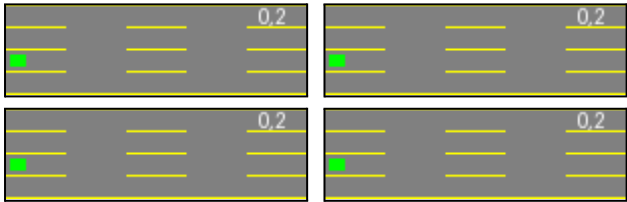

**Soft Update** → Updating model weights with the new weights after every episode however with a factor of  $\tau$ .

**Update Rule** -  $\text{target\_param} = \text{target\_param} - \tau * (\text{prev\_param} - \text{target\_param})$

Plots	Hyperparameters	Observation
	<ul style="list-style-type: none"> <li>- <math>\epsilon = 0.75</math></li> <li>- <math>df = 0.99</math></li> <li>- Batch = 256</li> <li>- Lr = <math>1e-3</math></li> <li>- Training Eps - 200K</li> <li>- Loss - MSE</li> </ul>	<p>Due to the constant epsilon, convergence is getting affected.</p>
 <p><u>Trajectory out of 10 output trajectories.</u></p>	<p><b>Strategy</b></p> <ul style="list-style-type: none"> <li>- Learning at the end of the episode</li> <li>- Replay buffer with size 1 lakh</li> <li>- Updation of model after every episode according to <b>Update Rule</b></li> </ul>	<p><b>Evaluation</b></p> <p>Averaged over 100 trajectories</p> <ul style="list-style-type: none"> <li>• Maximum Distance :- 71.87399999999997</li> <li>• Return Values of start state :- 1.7065604118142883</li> </ul>
<p><b>Visualize Lanes</b></p>

## Solution for Catastrophic Forgetting

### Implementation of Priority Experience Replay

Plots	Hyperparameters	Observation
	<ul style="list-style-type: none"> <li>- <math>\epsilon = 0.75</math></li> <li>- <math>df = 0.99</math></li> <li>- Batch = 256</li> <li>- <math>Lr = 1e-3</math></li> <li>- Training Eps - 200K</li> <li>- Loss - MSE</li> </ul>	<ul style="list-style-type: none"> <li>- Application of PER didn't help much.</li> <li>- Exploration rate need to be</li> </ul>
 <p><u>Trajectory out of 10 output trajectories.</u></p>	<b>Strategy</b> <ul style="list-style-type: none"> <li>- Learning at the end of the episode</li> <li>- <b>PER buffer with size 1 lakh</b></li> <li>- Updation of model after every 100 episode</li> </ul>	<b>Evaluation</b> <p><b>Averaged over 100 trajectories</b></p> <ul style="list-style-type: none"> <li>• Maximum Distance :- 44.75700000000002</li> <li>• Values of start state :- 0.2596145366224763</li> </ul>
<b>Visualize Lanes</b> 		
<b>Visualize Speed</b> 		

### c. Conclusions

- Prioritized Experience Replay converges very well.
- Soft Update of model gives good results on discrete case.
- Epsilon decay is the most important parameter to reduce degradation after gaining some experience.

## Part III: Deep Q-Learning (Neural Network as Q-Function)

### Best Parameters From Part I

- Learning rate ( $\alpha$ ) = **0.1**
- Discount Factor ( $\gamma$ ) = **0.9**
- Best Strategy = Variable  $\epsilon$  = **0.75**,  $\epsilon$ -decay-type = Exponential,  $\epsilon$ -decay = 1 - 1e-4

### Conclusions From Part II

- Prioritized Experience Replay converges very well.
- Soft Update of model gives good results on discrete case.
- Epsilon decay is the most important parameter to reduce degradation after gaining some experience
